

## 6.03 Virtual Lecture Notes – Heat Index

Sweating helps prevent overheating because the water in perspiration carries heat away from the body. But when the [relative humidity](#) is high it can “feel” hotter than it is because evaporation rate is reduced and less heat is removed. The Heat Index (also called the apparent temperature) is a way to calculate how hot it feels on days when there is also high humidity. If the temperature is less than 80° Fahrenheit or the humidity is less than 40%, there is no different between actual and apparent temperature (until the wind chill factor comes into play). The following table clearly indicates the risk imposed by high temperatures and high humidity.

**Likelihood of Heat Disorders with Prolonged Exposure or Strenuous Activity**

		Temperature (F)																	
		80	82	84	86	88	90	92	94	96	98	100	102	104	106	108	110		
H U M I D I T Y	40	80	81	83	85	88	91	94	97	101	105	109	114	119	124	130	136		
	45	80	82	84	87	89	93	96	100	104	109	114	119	124	130	137			
	50	81	83	85	88	91	95	99	103	108	113	118	124	130	137				
	55	81	84	86	89	93	97	101	106	112	117	124	130	137					
	60	82	84	88	91	95	100	105	110	116	123	129	137						
	65	82	85	89	93	98	103	108	114	121	128	136							
	70	83	86	90	95	100	105	112	119	126	134								
	75	84	88	92	97	103	109	116	124	132									
	80	84	89	94	100	106	113	121	129										
	85	85	90	96	102	110	117	126	135										
% R E L A T I V E	90	86	91	98	105	113	122	131											
	95	86	93	100	108	117	127												
	100	87	95	103	112	121	132												

**Caution**  
Fatigue Possible

**Extreme Caution**  
Sun stroke, muscle cramps and/or heat exhaustion possible

**Danger**  
Sun stroke, muscle cramps and/or heat exhaustion likely

**Extreme Danger**  
Heat stroke or sun stroke

Adapted from: <http://www.nws.noaa.gov/om/heat/index.shtml> and <http://www.floridadisaster.org/bpr/EMTOOLS/Severe/heatwave.htm>

For such a straightforward concept, the formula to calculate the [Heat Index](#) (HI) looks very complex; but it is just algebra. Temperature (T) is in degrees Fahrenheit and Relative Humidity (RH) is in percent. Examine the Heat Index formula closely and the 9 different components.

$$HI = -42.379 + 2.04901523T + 10.14333127R - 0.22475541TR - 6.83783 \times 10^{-3}T^2 - 5.481717 \times 10^{-2}R^2 + 1.22874 \times 10^{-3}T^2R + 8.5282 \times 10^{-4}TR^2 - 1.99 \times 10^{-6}T^2R^2$$

Several of the terms include scientific notation (e.g.  $10^{-3}$  and  $10^{-6}$ ), so you will need to review Lesson [3] in the IMACS unit on doubles in order to translate this formula into Java. In addition, several of the terms are raised to the second power (e.g.  $T^2$  and  $R^2$ ). You can handle exponents simply by multiplying the terms, or you can peek ahead and learn about the Math classes' `pow()` method. Use a calculator and determine the Heat Index for 92°F and 60% relative humidity. Verify your answer in the table above.
